

A 5 month old boy is brought in by his parents because of intermittent screaming. They got a bit concerned in the morning when he appeared to be less active than usual. Was not eating and for the last 2 hours started screaming intermittently and kicking with his legs up in the air. On the way to the hospital he vomited once. On examination he is lethargic but calm initially. HR is 140, BP 80/65. Abdomen is firm with a fullness felt in the RUQ. When you are examining him child starts to cry as above and vomits some bile stained fluid. Describe your initial management.
